Walkability and Green Space are Preventive Medicine

There is a public health crisis happening right now. Total health expenditure in Canada was estimated to be up to $253.5 billion ($6,839 per person) for 2018. This represents 11% of Canada’s gross domestic product according to the Canadian Institute for Health Information. For example, obesity, high blood pressure, and diabetes place tremendous pressure on our healthcare system (see Figure 1).

There is an increasing consensus that the postal code of the neighbourhood where we live is as important as our genetic code. Studies have shown that land-use decisions and transportation investments to enhance neighborhood walkability and access to green space can significantly affect how you travel and your physical activity, and exposure to air pollution, traffic safety and crime, and noise.

Very few studies have examined how transportation investment, neighbourhood walkability and access to green space are associated with less chronic disease and lower health care cost (see Figure 2). To date, existing evidence used to inform major transportation investment decisions have rarely accounted for the potential health impacts and related costs of these factors.

The Where Matters Study aims to incorporate health into local and regional policy-making by examining the multiple pathways linking the way our communities are planned and designed with people’s travel and physical activity patterns, chronic disease risk and health care cost.

Figure 1. Canadian health context using My Health, My Community survey for Metro Vancouver, and CCHS for BC and Canada.

Figure 2. Frank, L.D., Iroz-Elardo, N., MacLeod, K.E., & Hong, A. (2019). Pathways from built environment to health: A conceptual framework linking behavior and exposure-based impacts. Journal of Transport & Health, 12, 319-335.
The Where Matters Study is a unique partnership between the UBC Health and Community Design Lab and multiple government agencies and health authorities, including Vancouver Coastal Health, Fraser Health, Metro Vancouver, TransLink, and the City of Vancouver. The study had three aims:

1. To investigate the relationship between built and natural environment and health
2. To investigate how the relationships between built and natural environment and health vary across income and age groups
3. To investigate the extent to which walkable environments can reduce health care costs

The study used two existing and unique health datasets, the My Health, My Community Survey survey conducted between 2013 and 2014 (representing 33,000 individuals), and the BC Generations Project survey conducted between 2009 and 2013 (representing 18,000 individuals) that provided highly detailed information about people’s health & wellbeing and anonymous health records.

These datasets were then combined with a detailed built and natural environment database that measures neighbourhood walkability. Using this information, we studied the relationship between where people lived and how walkable their neighbourhood was to six health outcomes: (1) physical activity; (2) obesity; (3) diabetes; (4) heart disease; (5) stress; and (6) sense of community.

See the full technical report for more details. The Where Matter Study also built upon an existing study funded by the Canadian Institutes of Health Research (CIHR) to calculate the healthcare cost savings of living in a more walkable neighbourhood.
Measuring the Components of Walkability

Walkability is a measure of the physical characteristics of the urban environment at the local or neighbourhood level that support walking. In Metro Vancouver, walkability has been quantified by the Health and Community Design Lab using the method developed by Dr. Larry Frank and validated by numerous studies in North America. The walkability of an area is defined using four measures which, combined, create a **Walkability Index**.

- **Net residential density**: The concentration of dwelling units. Higher values indicate a greater number of dwelling units relative to the residential land area.
- **Commercial FAR**: The ratio between the total commercial floor area of a building to the land area of the property it is built on. Higher values indicate less surface parking and buildings set close to sidewalks and street.
- **Land use mix**: The balance between building floor areas of six land uses (retail, entertainment/recreation, civic/educational, office, single-family residential, and multi-family residential), providing more opportunities for different activities in the same area.
- **Intersection density**: The measure of road network connectivity. Higher values indicate smaller block sizes and a greater number of intersections.

Behaviour-Sheds

To measure how walkability differed across the region, we used every postal code in Metro Vancouver. To calculate the walkability index, we drew a one kilometre area around each postal code (also known as a street network buffer). The yellow dot is the center of the postal code. The bold dark lines represent the walkable road network segments. The green polygon is the 1 km buffer. We use the green polygon to measure the four components of walkability. This produces a highly detailed map of walkability across the region.

Five different types of neighbourhoods based on walkability

- **Car Dependent**
- **Somewhat Car Dependent**
- **Somewhat Walkable**
- **Moderately Walkable**
- **Walkable**
Access to Parks

Park access is a measure of the number of public parks that can be publicly accessed. To measure the number of parks, we used the street network buffer used to create the walkability index. Blue represents areas with a high number of parks (6 or more) and red represents zero to 1 parks nearby.

Regional Accessibility

Regional accessibility is a measure of ease of travel to major regional locations. Regional accessibility was defined as the number of major regional centres that can be reached by a 45-minute transit ride during the morning rush hour. Red represents areas with lower levels of regional accessibility and blue represents high accessibility.
Place Types by Walkability

* Numbers represent median value for each place type.

## Understanding how where you live matters for your health

### Park Access

People living in an area with many parks (6 or more) are **20% more likely to walk for leisure or recreation** and **33% more likely to meet the weekly recommended level of physical activity** compared to those living in an area with no parks.

People living in an area with many parks (6 or more) are **43% less likely to be obese** compared to those living in an area with no parks.

People living in an area with many parks (6 or more) are **37% less likely to have diabetes** compared to those living in an area with no parks.

People living in an area with many parks (6 or more) are **39% less likely to have heart disease** compared to those living in an area with no parks.

People living in an area with many parks (6 or more) are **19% less likely to have stressful days** compared to those living in an area with no parks.

People living in an area with many parks (6 or more) are **23% more likely to have a strong sense of community belonging** compared to those living in an area with no parks.
Understanding Economic Benefits for Chronic Disease

Our findings show that the type of neighbourhood you live in matters for your health. This means the type of investments we make in transportation infrastructure, parks, and land use actions will impact how much money we spend on health care. To show this relationship, we estimated annual direct cost to the health care system by linking the My Health My Community data with the Economic Burden of Illness in Canada and the Canadian Community Disease Surveillance System estimates (see link below) for diabetes, hypertension and heart disease in the lower mainland. Our findings suggest the type of neighbourhood you live in matters for your health.

### Diabetes

The estimated direct health care cost in a moderately walkable area is **23% less** than in a car dependent area. **48% less** is spent in a neighborhood with 1-2 parks nearby and **75% less** is spent in a neighborhood with 6 or more parks than in a neighborhood with 0-1 parks.

### Hypertension

The estimated direct healthcare cost in a walkable area is **47% less** than in a car dependent area. **59% less** is spent in a neighborhood with 1-2 parks nearby and **69% less** is spent in a neighborhood with 6 or more parks than in a neighborhood with 0-1 parks.

### Heart Disease

The estimated direct healthcare cost in a walkable area is **31% less** than in a car dependent area. **33% less** is spent in a neighborhood with 1-2 parks nearby and **69% less** is spent in a neighborhood with 6 or more parks than in a neighborhood with 0-1 parks.

---

So What? Policy Implications and Fiscal Impacts

Our findings reveal that the type of neighbourhood you live in matters for your health. For this reason, it is important to recognize that the type of investments we make in our transportation infrastructure, and the resulting land use patterns of our communities, will ultimately impact the money we individually and collectively as a society spend on healthcare.

In terms of walkability, people living in an urban centre have lower healthcare spending compared to those living in an exurban area for both diabetes and high blood pressure. In terms of park access, people living in an area with a high number of parks (6 or more) within a 1 kilometer distance have the lowest health care spending compared to those with no parks nearby.

Applying the Research

**Transit investment and TOD Business Case:** Policies to promote fixed guideway transit investment integrated with high density walkable development based on predicted reductions in chronic disease and associated health care cost savings.

**Green Space:** Investments in parks, green space, and open space programs to foster increased access to recreational environments based on predicted physical and mental (sense of community and social capital) benefits and health care cost savings.

**Active Transportation Planning:** Application of results demonstrating health and economic benefits of investing in active transportation to help justify increased funding for pedestrian and bike infrastructure and to help with defining needs and prioritizing investments.

**Land Use Scenario Planning:** Regulatory and fiscal policies to support increased access to shops and services and overall land use mix and densification and creation of contrasting future growth scenarios linked with health outcomes and costs.

**Health Equity:** Investing in underserved communities where transit, active transportation, greenspace, and policies to promote local access to shops and services are most needed to reduce the chronic disease burden born by the most disadvantaged.
“WHAT GETS MEASURED GETS DONE...”
